

IN423 - PW 03

HTTP POST and Network Analysis

1. Objectives and instructions

In this third practical work we will continue our previous work on TCP and HTTP. Follow the following instructions.

2. HTTP

In this part we will see how to enhance our HTTP server to make it able to send different kinds of data (encoding) and receive POST requests with data.

HTTP POST:

We are going to analyze the post requests made by the client. A post request is composed as follows: an http header ending with an empty line, followed by the data.

- 1 - Adapt your http server so it displays the entire requests sent by the client.
- 2- Start your http server
- 3 - Use your web browser to open the control.html page and click on one button.
- 4 – Take a look at the POST request (print by the server)

2.1 What is the value (data) associated with the post? Where it is located on the request body (i.e. received message) ?

The data is "move=forward". It is located after a blank after the header

2.2 Adapt the server so that it prints "move forward", "move backward" etc. depending on the post request.

Nb: to separate the HTTP header part from the HTTP data part that contain the post data (i.e. “move backward” etc.) you should use the sequence `asciisep`

= `“\r\n\r\n”`

as the separator.

As the request and the data are all made of ascii text you could use it as string manipulation. But it could be better to directly split the raw binary request with

`binsep = b“\r\n\r\n”`

2.3 Adapt your server so that replies to the post request with an HTTP 200 message and the control.html page as data.

See code

HTTP 304 Not Modified:

What is a cache?

A cache is information stored on the client side or on an intermediate server to increase the access speed to this information if it was not modified since last access.

For web content this is a common way to accelerate the web-page load time.

In the HTTP 200 response: activate cache control

To enable cache management the HTTP 200 messages from the server must contain cache control information.

There are different possible options, but here we will only add the following option in the HTTP 200 responses to activate the cache management on the client side:

`Cache-Control: max-age=<seconds> (put`

`3600 for <seconds> value).`

You must also indicate the expiration date for the web-resource by adding the expires field:

`Expires: <http-date> Example:`

`Expires: Wed, 21 Oct 2015 07:28:00 GMT`

Now use the 304 not modified message

If the client uses the

`If-Modified-Since: <label-day>, <day> <month> <year>
<hour>:<minute>:<second> GMT`

Example:

If-Modified-Since: Wed, 21 Oct 2015 07:28:00 GMT

Here is an example of an HTTP 304 message that tells the client that the requested resource is not modified and that it should not refresh the page.

```
HTTP/1.1 304 Not Modified\r\n
Date : Mon, Apr 26 07:43:53 2021 GMT\r\n
Expire : Mon, Apr 26 08:43:53 2021 GMT\r\n
Etag : ipsavl
Cache-control : max-age=3600\r\n
\r\n
```

2.4 Use this example but adapt values of Date and Expires options to respond to the image request when it has already been sent.

!\\ For now this part is only working with google chrome !

The date should be the current date: `time.asctime(time.gmtime())`

The Expires field should be filled with:

`time.asctime(time.gmtime(time.time()+3600)) + " GMT"`

explanation:

`time.time()` gives current time in seconds

`time.time()+3600` gives current time in seconds + 3600 seconds

`time.gmtime()` translate time to GMT `time.asctime()` make it a string

3. Network analysis

Use Wireshark to capture POST requests and responses of your server.

3.1 What is the filter you have used

```
http.request.method == "POST"
```

3.2 Copy your results here:

```
+> 1337 14.715485 127.0.0.1 127.0.0.1 HTTP 935 POST /control.html HTTP/1.1
